

# Determining the station catchment area with walking distance distribution

Daisuke Hasegawa (CREI)

2024/03/29 CREI International Forum

# Importance of station catchment area

## • Impact of Transportation Hubs on Urban Development

- Stations serve as critical transportation hub.
  - Attract a diverse population of residents and visitors.
  - Urban design in major Japanese cities is centered around stations.

## • The Economic Significance of Station Proximity

- Distance to stations plays a vital role in various economic activities related to real estate.
  - Office rent, hotel accommodation rates, residential property prices, and parking fees.

## • It is important to define station catchment area

- access to station on foot

Minutes walk to station

# Define of station catchment areas

- **Deductive definition of station catchment area**

- Spatial calculation under the assumption for movement
- Distance metrics:
  - Euclid/Manhattan distance
  - Network distance...

- The size of the catchment area are depending on the environment around the station.

- Facility location, Population composition
- Walkability(Wide of pedestrian, Green-space..)

- Data-driven approaches are necessary to determine the correct station catchment area

- Using GPS trajectory data

- Roads and pathways
- 5 minutes walk - Underground station
  - 5 minutes walk - Ground-level station
  - 10 minutes walk - Underground station
  - 10 minutes walk - Ground-level station

Catchment area using network distance  
(J. L. E. Andersen & A. Landex.(2008))

# Previous studies

- **Survey-Based Data:**(Biba.et.al. 2010, Pueboobpaphan.et.al. 2022)
  - Limitation in investigating the actual distance.
  - Costly and not easily updated frequently for monitoring.
- **GPS data for Trip Length Analysis:**(Zuo et al. 2018)
  - They designed a GPS-based survey only for their research,
  - The number of samples needed to be more to discuss the differences among stations.

## **Our Research Motivation:**

Monitoring of catchment areas in many stations from GPS-based big trajectory data.

# Aim of research

- **Objective:**

- Investigate walking distance to railway stations using GPS-based Big Data in Tokyo
- Understand ranges and distribution of distances within the station catchment area
  - Classification of stations from distance distribution

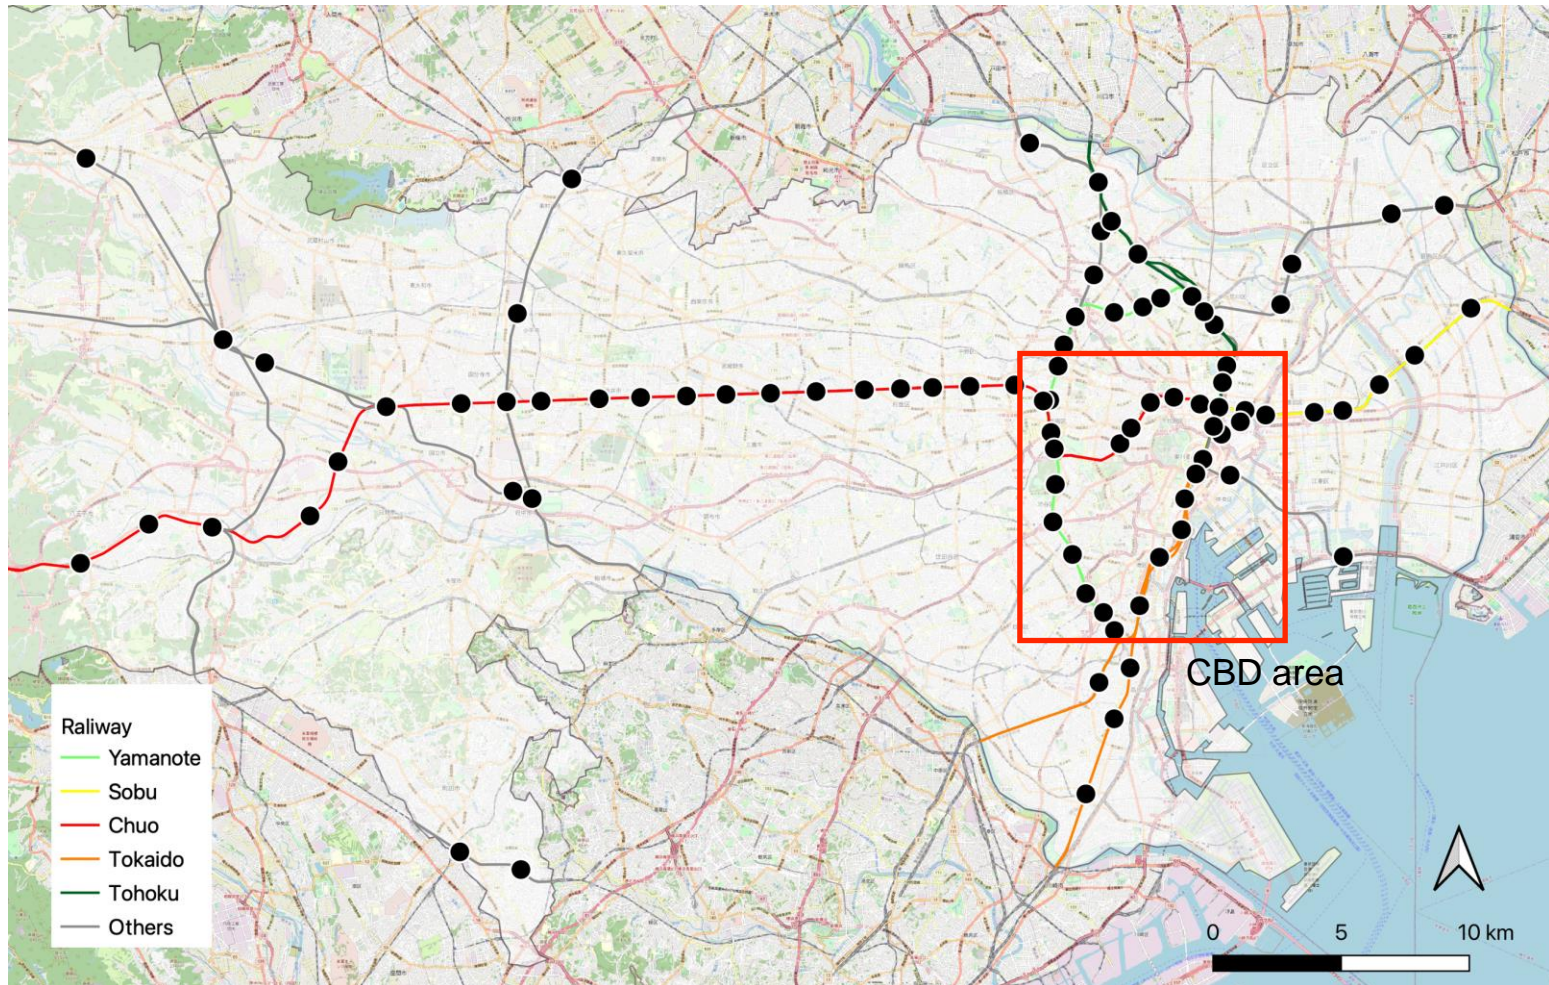

- **Contributions:**

- Provide method of processing and analyzing detailed spatial-temporal Information:
  - Use individual trajectories to gather fine-scale spatiotemporal information from stations.
  - Categorize stations based on distance distribution and analyze catchment area range.
- The Value of analysis in Tokyo:
  - Mature city (High TOD Level, Walkability, Aging of population)

# Target area

- 88 stations in Tokyo across 15 lines operated by Japan Railway (JR).

# GPS data source

- Point-type floating population data (Agoop Corp. 2019).
  - Large-scale and fine-grained point data from smartphone
  - It is used for understanding travel behavior (Joo et al. 2022, Kato et al. 2022, Yamagata et al. 2019)
- Data attributes
  - User ID, time, latitude, and longitude
  - Intervals of data transmission are less than 10 minutes
- Period
  - April 16 to April 29, 2019, between 6:00 and 24:00.
  - Approximately 1.2 million unique user IDs in the target metro area.

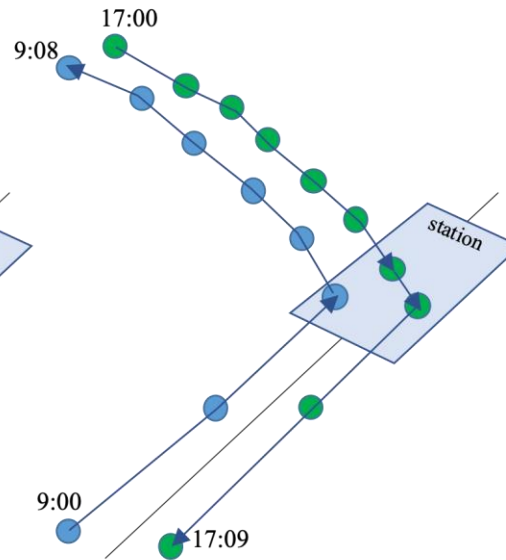

# GPS data processing

- Extracting the walking trip with three steps

1. Connect in each user ID points in chronological order

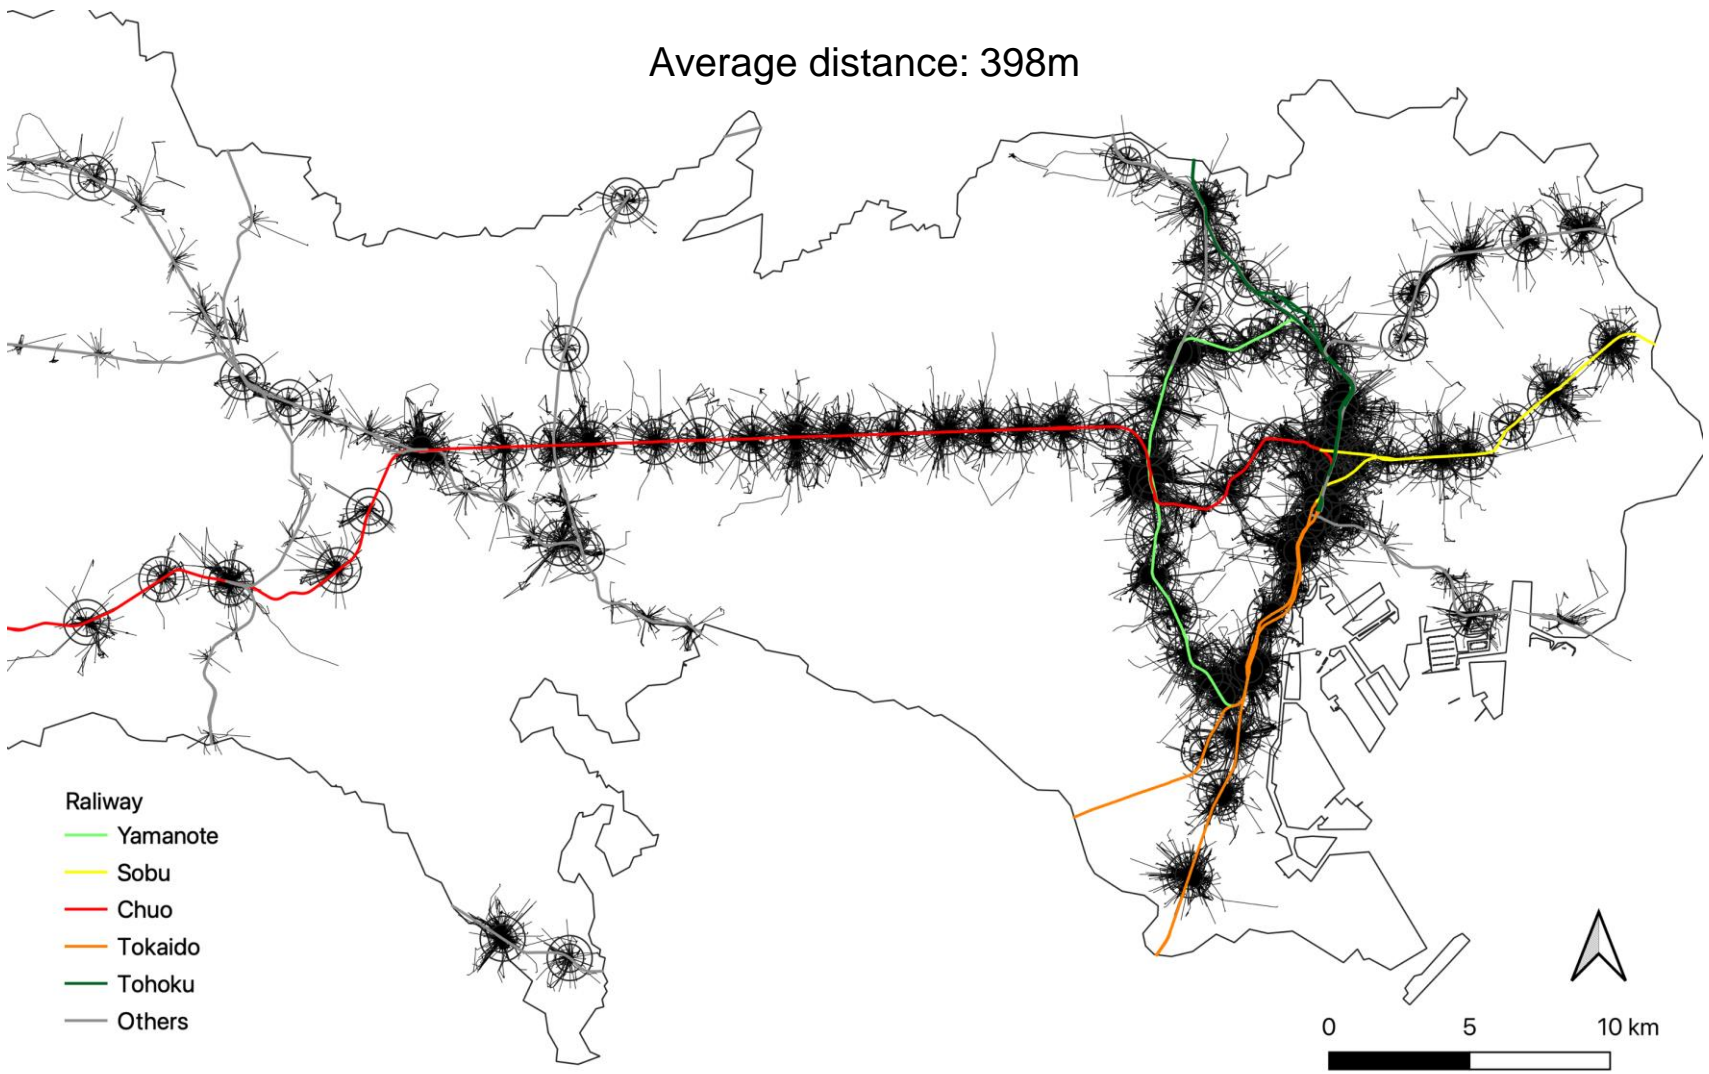

2. Separate lines

3. Select walking trips

Average distance: 398m

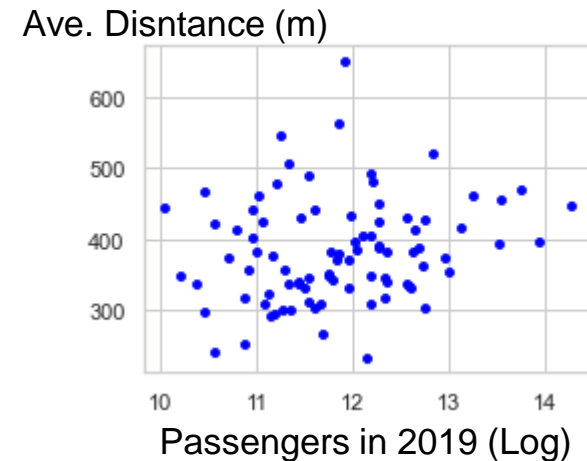

# Walking trip distance

- Distance of walking trip is Euclid distance from station polygon to the farthest point

- It is no clear relationship between distance and size of station.

# Walking distance distribution

- Create a probability distribution (walking distance distribution) by summing trip lengths for each distance band
  - Characterize each station by probability decay

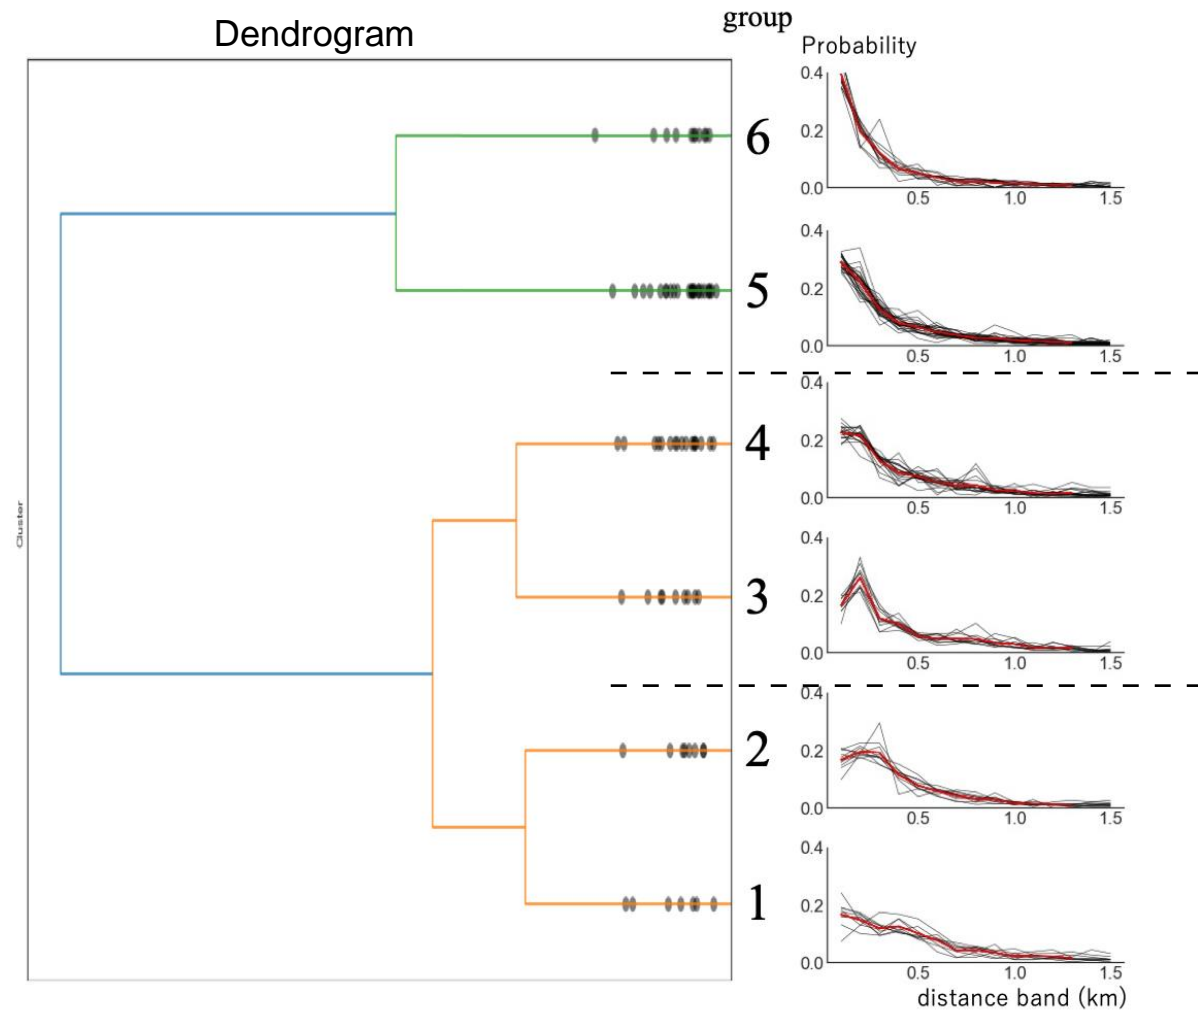

# Distance distribution

- Walking distance distributions of the 88 stations
  - Trend of more short-distance trips but the rate of decay in trip frequency varies among stations.
- Classify the walking distance distribution pattern

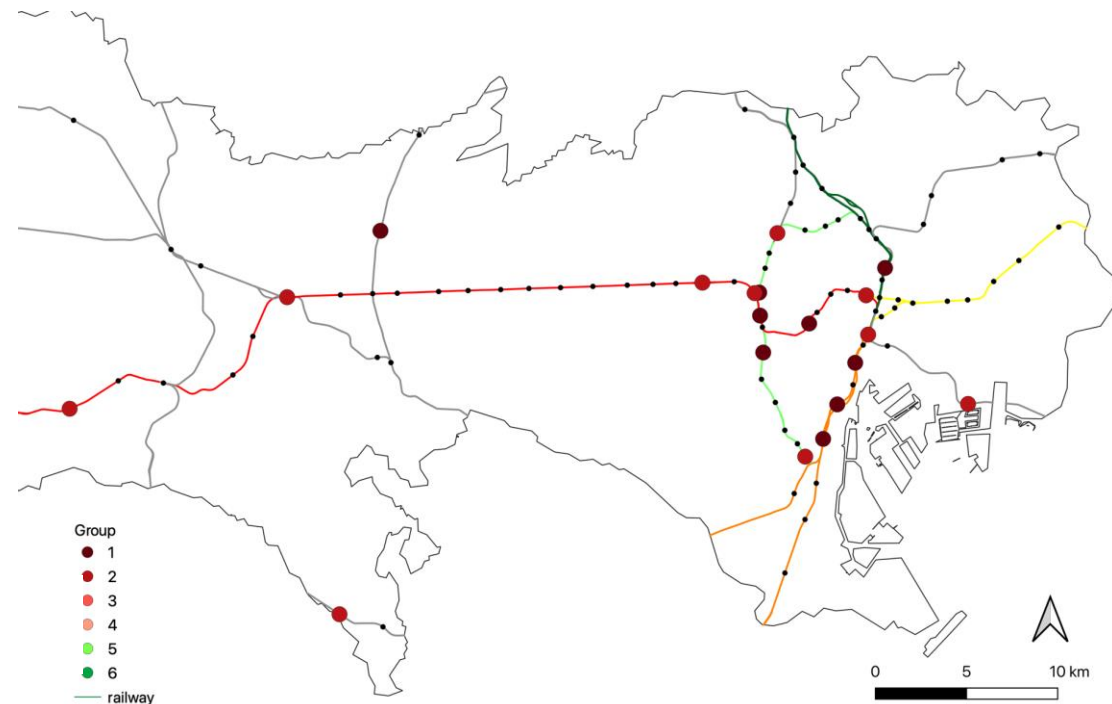

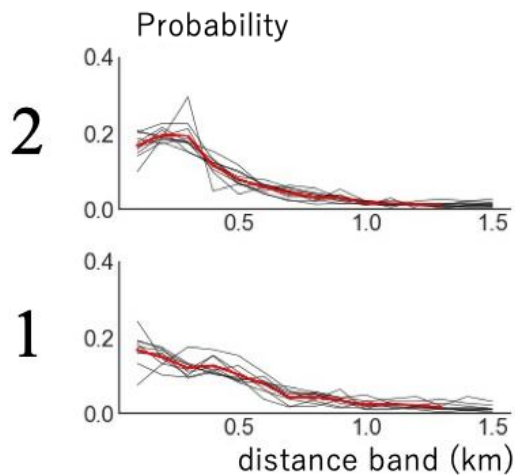

# Result of classification

- 6 groups based on hierarchical clustering method(Dendrogram).
- Trend of catchment
  - Large: Group1,2
  - Middle: Group3,4
  - Small: Group5,6

# Spatial distribution of groups

- Large catchment areas (Group 1, 2)
  - Group 2 has relatively concentrated distribution until 500 m.
  - Almost locate in CBD area

# Spatial distribution of groups

- Large catchment areas(Group 1, 2)
  - Large station in CBD
  - Business area, Downtown are near station

<https://livejapan.com/ja/in-tokyo/in-pref-tokyo/in-shinjuku/article-a0001085/>

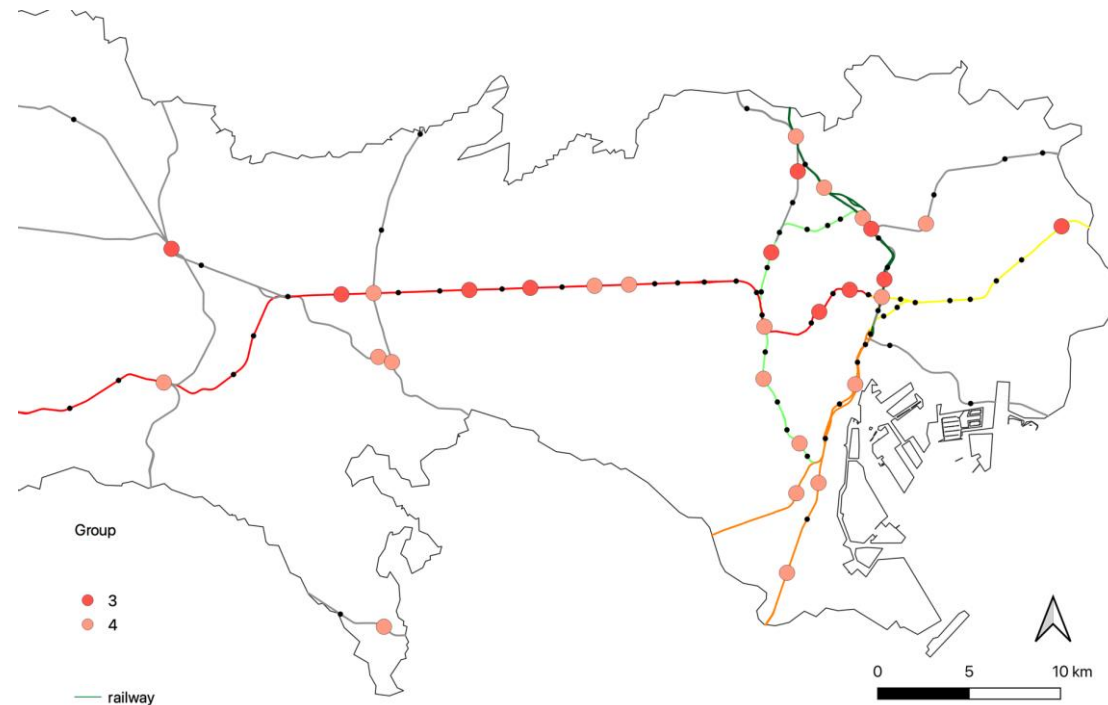

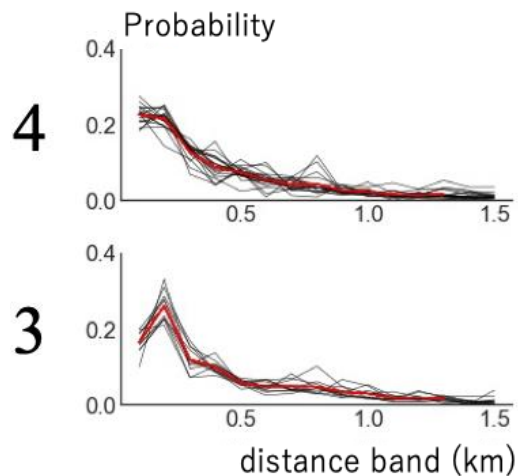

Shinjuku station (Group 1)

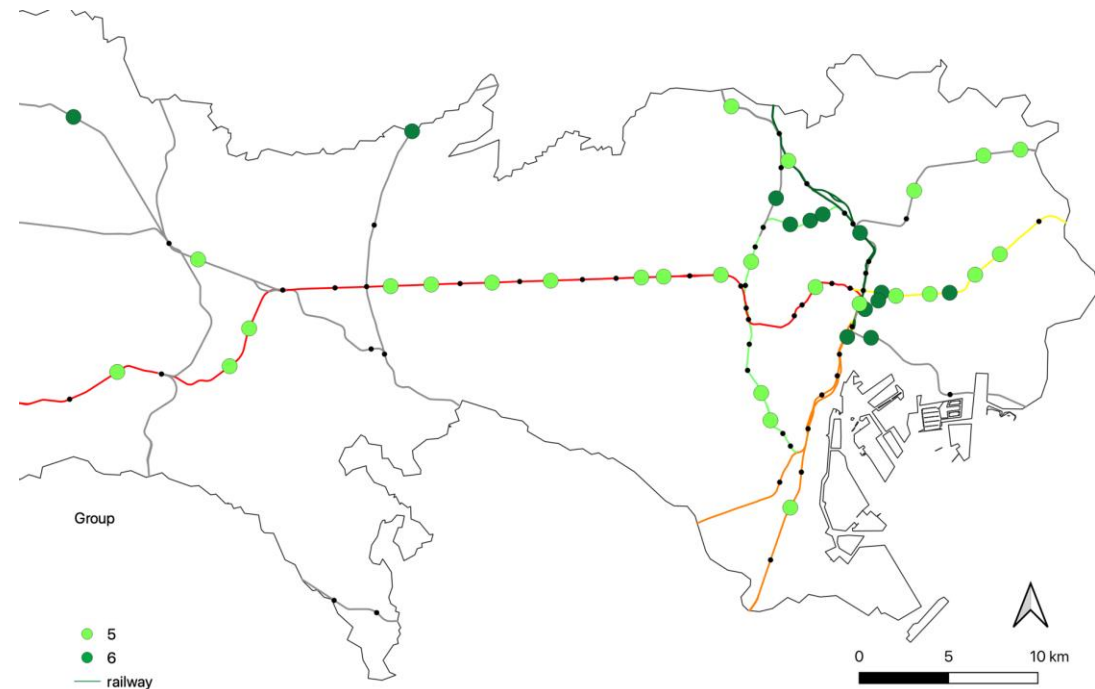

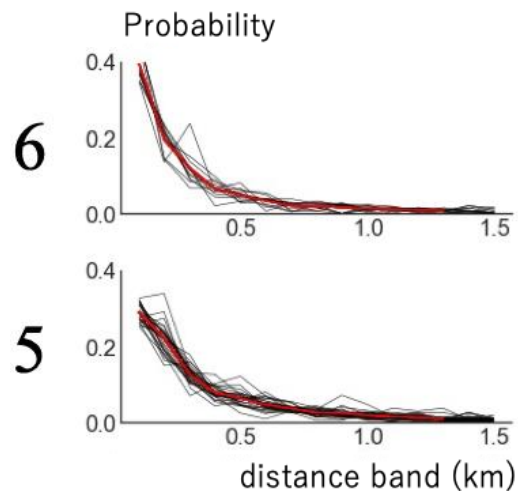

# Spatial distribution of groups

- Middle catchment areas(Group 3,4)
  - Catchment area are shorter than Group1,2
  - Group3 has higher concentrated distribution within 200 m.

# Spatial distribution of groups

- Small catchment areas (Group 5,6)
  - Short average distances They are almost residential area around stations.

# Conclusion

- This study examines station catchment areas in Tokyo, considering walking distance for Transit-Oriented Development (TOD).
- **Key findings include:**
  1. **GPS-based Walking Distance Analysis**
    - GPS analysis accurately identifies walking distances from stations, enabling effective monitoring of spatial planning effects.
  2. **Variation in average walking distance**
    - Average walking distances vary by location, ranging from 233m to 651m for target stations, informing built environment and transit service considerations.
  3. **Importance of Distance Distribution**
    - Distance distribution analysis provides valuable insights beyond averages, resulting in the classification of transit stations into six groups with similar average distances but different distributions.

# On-going works

## • Why was the catchment area created?

- Development Pedestrian Movement Index
- Impact of TOD attributes (road network, facility density etc.) varied walking pattern
